GUI vs. CLI
8/29/26

When I did some research on YouTube about GUI and CLI, I learned that a GUI, or graphical user interface, and a CLI, or command-line interface, are two different ways of interacting with a computer. A GUI allows you to use visual things such as windows, icons, buttons, and menus. A CLI uses typed commands in the terminal to tell the computer what you want it to do.

One major difference between a GUI and a CLI is how you communicate with the computer. With a GUI, I can open a folder by clicking on it and move files around by dragging them, allowing me to interact with the computer with minimal keyboard input. With a CLI, I would type commands to navigate through folders, create files, or move files. A GUI is generally easier for someone who is new to computers because you can see the options that are available to you.

A CLI can take more time to learn because you have to know the correct commands. However, once you are familiar with those commands, a CLI can be very fast and useful, especially when programming or working with many files. A GUI is more visual and can feel more comfortable for beginners, while a CLI gives you more direct control through commands.

Personally, I think a GUI is easier for me to use right now because I am still learning about coding. I like being able to see my files, folders, and different options instead of having to remember commands. However, I think learning how to use a CLI will be useful as I continue learning programming. After watching the video, I also understand that neither one is always better. It depends on what you are trying to do, and sometimes a GUI is the better tool while other times a CLI is more useful. Both interfaces have their advantages, and I think knowing how to use both will help me become more comfortable working with computers.
